Hintergrundinformationen

Thymosin beta 4 (Tβ4), encoded by TMSB4X gene, is an actin sequestering protein which plays an important role in the organization of the cytoskeleton. Numerous studies have demonstrated the effects of Tβ4 on cell migration, proliferation, apoptosis and inflammation after exogenous treatment (PMID: 22652458). Recently, novel findings provided compelling evidence that Tβ4 played a key role in facilitating tumor metastasis and angiogenesis. It has been found that Tβ4 expressed increasingly in a number of metastatic tumors, thus providing a potential target of opportunity for cancer management, especially for cancer metastasis therapy (PMID: 22856429).
