Informations générales

The Wnt gene family encodes secreted signaling molecules that bind to frizzled receptors and influence oncogenesis and developmental processes, including regulation of cell fate and patterning during embryogenesis. Wnt7a is normally expressed in several organs, including the lung, testis, lymph node, and brain. As an oncogenic autocrine glycoprotein, Wnt7a promotes tumor invasion and distant metastasis with cancer-associated fibroblasts. Wnt7b is required for endothelial cells derived from pluripotent stem cells to acquire blood-brain barrier properties and may play an important role in the development of myopia in humans. This antibody can both recognize WNT7A and WNT7B.
