Informations générales

Signal recognition particle(SRP) acts in three distinct ways: 1 it binds to the signal sequence of the nascent polypeptide to be translocated, which is exposed on the surface of the translating ribosome; 2 it temporarily retards the nascent polypeptide from further elongation; 3 it mediates docking of the SRP-ribosome-nascent polypeptide chain complex to the RER membrane via the heterodimeric SRP-receptor (SR). SRP14, also named as 18 kDa Alu RNA-binding protein, is a 136 amino acid protein. Signal recognition particle consists of a 7S RNA molecule of 300 nucleotides and six protein subunits: SRP72, SRP68, SRP54, SRP19, SRP14 and SRP9. SRP14 protein is a component of signal-recognition-particle that has a crucial role in targeting secretory proteins to the rough endoplasmic reticulum membrane. SRP9 together with SRP14 and the Alu portion of the SRP RNA, constitutes the elongation arrest domain of SRP. SRP14 form a heterodimer with SRP9, which recognizes Alu RNA and the related 7SL RNA.
