Background Information

PAM (Peptidyl-glycine alpha-amidating monooxygenase) is a multifunctional protein containing 2 enzymes, PHM and PAL. The PAM protein containing the peptide encoded by exon A (Type B mRNA) is cleaved to form 41- and 43-kDa proteins, and the 75 kDa PAM protein is determined by lacking antigenic exon B (Type A) (PMID:1740449). The substrate specificity of PAM is broad, and production of all α-amidated peptides may be dependent upon proteins encoded by the single copy PAM gene (PMID:8436961). It has 6 isoforms produced by alternative splicing.
